

FinTrust Digital Bank – Business Findings

Business Question

Why are there a high number of failed transactions at FinTrust Digital Bank?

Profile Summary

The analysis covers 12,000 transactions across multiple customer segments, account types, channels, and device types.

- Transaction activity was distributed across a diverse mix of customer segments, with Everyday and Premium customers representing substantial shares of the transaction population.
- Digital banking channels and mobile devices accounted for a significant proportion of transaction activity, reflecting the range of electronic banking activity captured in the dataset.
- A broad range of transaction types was observed, providing a diverse basis for assessing transaction failure patterns.

Key Insights

- Risk-reviewed transactions recorded a higher failure rate (7.23%) than non-risk-reviewed transactions (4.77%).
- iOS transactions recorded the highest failure rate among device categories at 5.75%, although the difference across device types was relatively modest.
- Failure rates were highest during the Afternoon (5.93%) and Evening (5.90%) periods.
- Domestic transactions recorded a higher failure rate (5.36%) than international transactions (2.50%), although international transactions represented a much smaller share of the transaction population.

Business Findings

Finding 1: Risk-Reviewed Transactions Experienced Higher Failure Rates

Evidence

Risk-reviewed transactions recorded a failure rate of 7.23%, compared with 4.77% for non-risk-reviewed transactions.

Business Meaning

Risk-reviewed transactions had a higher observed failure rate than non-risk-reviewed transactions. This indicates an association between risk-review status and transaction failures. Further investigation could examine whether additional risk controls, authentication requirements, or other characteristics of risk-reviewed transactions contribute to the higher failure rate.

Finding 2: iOS Transactions Recorded the Highest Device-Related Failure Rate

Evidence

iOS transactions recorded a failure rate of 5.75%, the highest among all device categories. Within the risk-reviewed population, the iOS failure rate increased to 9.26%.

Business Meaning

iOS transactions had the highest observed failure rate among the device categories analysed, with an even higher rate among risk-reviewed iOS transactions. Further investigation of iOS transaction behaviour, authentication processes, and transaction outcomes may help identify factors associated with the elevated failure rate.

Finding 3: Failure Rates Were Highest During Afternoon and Evening Periods

Evidence

The highest failure rates were recorded during the Afternoon (5.93%) and Evening (5.90%), compared with Morning (4.83%) and Night (4.33%).

Business Meaning

Transaction failures were more common during the afternoon and evening periods. Monitoring transaction performance during these periods may help determine whether operational, behavioural, or system-related factors are contributing to the higher failure rates.

Finding 4: Domestic Transactions Recorded Higher Failure Rates than International Transactions

Evidence

Domestic transactions recorded a failure rate of 5.36%, compared with 2.50% for international transactions.

Business Meaning

Domestic transactions had a higher observed failure rate than international transactions. Further analysis of domestic transaction types, channels, devices, and risk-review status could help identify factors associated with this difference. The relatively smaller volume of international transactions should also be considered when interpreting the comparison.

Finding 5: Mobile Banking Represented a Significant Share of Transaction Activity

Evidence

Mobile banking channels accounted for a substantial proportion of total transaction activity, while mobile devices, particularly Android and iOS, represented the largest device categories.

Business Meaning

A significant proportion of transactions occurs through mobile channels. Therefore, maintaining reliable mobile transaction performance is important for overall transaction success and customer experience. Monitoring mobile transaction outcomes by device, channel, transaction type, and risk-review status could help identify areas requiring further investigation.

Conclusion

The analysis identified several factors associated with elevated transaction failure rates, including risk-review status, device type, time of day, and transaction scope. Mobile channels also represented a substantial proportion of transaction activity, making mobile transaction reliability an important consideration for overall customer experience.

These findings provide a basis for further investigation and targeted operational improvements aimed at improving transaction reliability, reducing failed transactions, and enhancing customer experience. The findings represent observed patterns in the available transaction data and should be investigated further before attributing failures to specific operational or technical causes.
